## 7.64.1 Function Documentation

### 7.64.1.1 `NppStatus nppiSwapChannels_16s_AC4R (const Npp16s * pSrc, int nSrcStep, Npp16s * pDst, int nDstStep, NppiSize oSizeROI, const int aDstOrder[3])`

4 channel 16-bit signed integer source image to 4 channel destination image with destination alpha channel unaffected.

#### Parameters:

*pSrc* Source-Image Pointer.

*nSrcStep* Source-Image Line Step.

*pDst* Destination-Image Pointer.

*nDstStep* Destination-Image Line Step.

*oSizeROI* Region-of-Interest (ROI).

*aDstOrder* Host memory integer array describing how channel values are permuted. The n-th entry of the array contains the number of the channel that is stored in the n-th channel of the output image. E.g. Given an RGBA image, *aDstOrder* = [2,1,0] converts this to BGRA channel order. In the AC4R case, the alpha channel is always assumed to be channel 3.

#### Returns:

[Image Data Related Error Codes](#), [ROI Related Error Codes](#)

### 7.64.1.2 `NppStatus nppiSwapChannels_16s_C3C4R (const Npp16s * pSrc, int nSrcStep, Npp16s * pDst, int nDstStep, NppiSize oSizeROI, const int aDstOrder[4], const Npp16s nValue)`

3 channel 16-bit signed integer source image to 4 channel destination image.

#### Parameters:

*pSrc* Source-Image Pointer.

*nSrcStep* Source-Image Line Step.

*pDst* Destination-Image Pointer.

*nDstStep* Destination-Image Line Step.

*oSizeROI* Region-of-Interest (ROI).

*aDstOrder* Host memory integer array describing how channel values are permuted. The n-th entry of the array contains the number of the channel that is stored in the n-th channel of the output image. E.g. Given an RGB image, *aDstOrder* = [3,2,1,0] converts this to VBGR channel order.

*nValue* (V) Single channel constant value that can be replicated in one or more of the 4 destination channels. *nValue* is either written or not written to a particular channel depending on the *aDstOrder* entry for that destination channel. An *aDstOrder* value of 3 will output *nValue* to that channel, an *aDstOrder* value greater than 3 will leave that particular destination channel value unmodified.

#### Returns:

[Image Data Related Error Codes](#), [ROI Related Error Codes](#)

## 7.68 Convolution

### Filter

## FilterBorder

General purpose 2D convolution filter with border control.

Pixels under the mask are multiplied by the respective weights in the mask and the results are summed. Before writing the result pixel the sum is scaled back via division by nDivisor. If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

Note: The new Border versions of all Filter functions are in beta test in the 6.0 release of NPP.

## FilterBorder32f

General purpose 2D convolution filter using floating-point weights with border control.

Pixels under the mask are multiplied by the respective weights in the mask and the results are summed. Before writing the result pixel the sum is scaled back via division by nDivisor. If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

### 7.71.1 Detailed Description

Fixed filters perform linear filtering operations (i.e. convolutions) with predefined kernels of fixed sizes.

Some of the fixed filters have versions with border control. For these functions, if any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported for these functions.

### 7.72.1 Detailed Description

Routines manipulating an image's geometry.

### 7.72.2 Geometric Transform API Specifics

This section covers some of the unique API features common to the geometric transform primitives.

#### 7.72.2.1 Geometric Transforms and ROIs

Geometric transforms operate on source and destination ROIs. The way these ROIs affect the processing of pixels differs from other (non geometric) image-processing primitives: Only pixels in the intersection of the destination ROI and the transformed source ROI are being processed.

The typical processing proceeds as follows:

1. Transform the rectangular source ROI (given in source image coordinates) into the destination image space. This yields a quadrilateral.
2. Write only pixels in the intersection of the transformed source ROI and the destination ROI.

#### 7.72.2.2 Pixel Interpolation

The majority of image geometry transform operation need to perform a resampling of the source image as source and destination pixels are not coincident.

NPP supports the following pixel interpolation modes (in order from fastest to slowest and lowest to highest quality):

- nearest neighbor
- linear interpolation
- cubic convolution
- supersampling
- interpolation using Lanczos window function

### 7.73.1 Detailed Description

`ResizeSqrPixel` supports the following interpolation modes:.

```
NPPI_INTER_NN
NPPI_INTER_LINEAR
NPPI_INTER_CUBIC
NPPI_INTER_CUBIC2P_BSPLINE
NPPI_INTER_CUBIC2P_CATMULLROM
NPPI_INTER_CUBIC2P_B05C03
NPPI_INTER_SUPER
NPPI_INTER_LANCZOS
```

`ResizeSqrPixel` attempts to choose source pixels that would approximately represent the center of the destination pixels. It does so by using the following scaling formula to select source pixels for interpolation:

```
nAdjustedXFactor = 1.0 / nXFactor;
nAdjustedYFactor = 1.0 / nYFactor;
nAdjustedXShift = nXShift * nAdjustedXFactor + ((1.0 - nAdjustedXFactor) * 0.5);
nAdjustedYShift = nYShift * nAdjustedYFactor + ((1.0 - nAdjustedYFactor) * 0.5);
nSrcX = nAdjustedXFactor * nDstX - nAdjustedXShift;
nSrcY = nAdjustedYFactor * nDstY - nAdjustedYShift;
```

In the `ResizeSqrPixel` functions below source image clip checking is handled as follows:

If the source pixel fractional x and y coordinates are greater than or equal to `oSizeROI.x` and less than `oSizeROI.x + oSizeROI.width` and greater than or equal to `oSizeROI.y` and less than `oSizeROI.y + oSizeROI.height` then the source pixel is considered to be within the source image clip rectangle and the source image is sampled. Otherwise the source image is not sampled and a destination pixel is not written to the destination image.

### 7.73.2 Error Codes

The resize primitives return the following error codes:

- `NPP_WRONG_INTERSECTION_ROI_ERROR` indicates an error condition if `srcROIRect` has no intersection with the source image.

- [NPP\\_RESIZE\\_NO\\_OPERATION\\_ERROR](#) if either destination ROI width or height is less than 1 pixel.
- [NPP\\_RESIZE\\_FACTOR\\_ERROR](#) Indicates an error condition if either *nXFactor* or *nYFactor* is less than or equal to zero.
- [NPP\\_INTERPOLATION\\_ERROR](#) if *eInterpolation* has an illegal value.
- [NPP\\_SIZE\\_ERROR](#) if source size width or height is less than 2 pixels.

### 7.74.1 Detailed Description

This function has been deprecated.

ResizeSqrPixel provides the same functionality and more.

Resize supports the following interpolation modes:

```
NPPI_INTER_NN
NPPI_INTER_LINEAR
NPPI_INTER_CUBIC
NPPI_INTER_SUPER
NPPI_INTER_LANCZOS
```

Resize uses the following scaling formula to select source pixels for interpolation:

```
scaledSrcSize.width = nXFactor * srcRectROI.width;
scaledSrcSize.height = nYFactor * srcRectROI.height;
nAdjustedXFactor = (srcRectROI.width - 1) / (scaledSrcSize.width - 1);
nAdjustedYFactor = (srcRectROI.height - 1) / (scaledSrcSize.height - 1);
nSrcX = nAdjustedXFactor * nDstX;
nSrcY = nAdjustedYFactor * nDstY;
```

In the Resize functions below source image clip checking is handled as follows:

If the source pixel fractional x and y coordinates are greater than or equal to oSizeROI.x and less than oSizeROI.x + oSizeROI.width and greater than or equal to oSizeROI.y and less than oSizeROI.y + oSizeROI.height then the source pixel is considered to be within the source image clip rectangle and the source image is sampled. Otherwise the source image is not sampled and a destination pixel is not written to the destination image.

## 7.74.2 Error Codes

The resize primitives return the following error codes:

- [NPP\\_WRONG\\_INTERSECTION\\_ROI\\_ERROR](#) indicates an error condition if srcROIRect has no intersection with the source image.
- [NPP\\_RESIZE\\_NO\\_OPERATION\\_ERROR](#) if either destination ROI width or height is less than 1 pixel.
- [NPP\\_RESIZE\\_FACTOR\\_ERROR](#) Indicates an error condition if either nXFactor or nYFactor is less than or equal to zero.
- [NPP\\_INTERPOLATION\\_ERROR](#) if eInterpolation has an illegal value.
- [NPP\\_SIZE\\_ERROR](#) if source size width or height is less than 2 pixels.

### 7.75.1 Detailed Description

Remap supports the following interpolation modes:.

NPPI\_INTER\_NN NPPI\_INTER\_LINEAR NPPI\_INTER\_CUBIC NPPI\_INTER\_CUBIC2P\_BSPLINE  
NPPI\_INTER\_CUBIC2P\_CATMULLROM NPPI\_INTER\_CUBIC2P\_B05C03 NPPI\_INTER\_-  
LANCZOS

Remap chooses source pixels using pixel coordinates explicitly supplied in two 2D device memory image arrays pointed to by the pXMap and pYMap pointers. The pXMap array contains the X coordinated and the pYMap array contains the Y coordinate of the corresponding source image pixel to use as input. These coordinates are in floating point format so fraction pixel positions can be used. The coordinates of the source pixel to sample are determined as follows:

$nSrcX = pXMap[nDstX, nDstY]$   $nSrcY = pYMap[nDstX, nDstY]$

In the Remap functions below source image clip checking is handled as follows:

If the source pixel fractional x and y coordinates are greater than or equal to oSizeROI.x and less than oSizeROI.x + oSizeROI.width and greater than or equal to oSizeROI.y and less than oSizeROI.y + oSizeROI.height then the source pixel is considered to be within the source image clip rectangle and the source image is sampled. Otherwise the source image is not sampled and a destination pixel is not written to the destination image.

### 7.75.2 Error Codes

The remap primitives return the following error codes:

- **NPP\_WRONG\_INTERSECTION\_ROI\_ERROR** indicates an error condition if srcROIRect has no intersection with the source image.
- **NPP\_INTERPOLATION\_ERROR** if eInterpolation has an illegal value.

### Affine Transform

Transforms (warps) an image based on an affine transform.

The affine transform is given as a  $2 \times 3$  matrix  $C$ . A pixel location  $(x, y)$  in the source image is mapped to the location  $(x', y')$  in the destination image. The destination image coordinates are computed as follows:

$$x' = c_{00} * x + c_{01} * y + c_{02} \quad y' = c_{10} * x + c_{11} * y + c_{12} \quad C = \begin{bmatrix} c_{00} & c_{01} & c_{02} \\ c_{10} & c_{11} & c_{12} \end{bmatrix}$$

Affine transforms can be understood as a linear transformation (traditional matrix multiplication) and a shift operation. The  $2 \times 2$  matrix

$$L = \begin{bmatrix} c_{00} & c_{01} \\ c_{10} & c_{11} \end{bmatrix}$$

represents the linear transform portion of the affine transformation. The vector

$$v = \begin{pmatrix} c_{02} \\ c_{12} \end{pmatrix}$$

represents the post-transform shift, i.e. after the pixel location is transformed by  $L$  it is translated by  $v$ .

## Backwards Affine Transform

Transforms (warps) an image based on an affine transform.

The affine transform is given as a  $2 \times 3$  matrix  $C$ . A pixel location  $(x, y)$  in the source image is mapped to the location  $(x', y')$  in the destination image. The destination image coordinates fulfill the following properties:

$$x = c_{00} * x' + c_{01} * y' + c_{02} \quad y = c_{10} * x' + c_{11} * y' + c_{12} \quad C = \begin{bmatrix} c_{00} & c_{01} & c_{02} \\ c_{10} & c_{11} & c_{12} \end{bmatrix}$$

In other words, given matrix  $C$  the source image's shape is transformed to the destination image using the inverse matrix  $C^{-1}$ :

$$M = C^{-1} = \begin{bmatrix} m_{00} & m_{01} & m_{02} \\ m_{10} & m_{11} & m_{12} \end{bmatrix} \quad x' = m_{00} * x + m_{01} * y + m_{02} \quad y' = m_{10} * x + m_{11} * y + m_{12}$$

## Quad-Based Affine Transform

Transforms (warps) an image based on an affine transform.

The affine transform is computed such that it maps a quadrilateral in source image space to a quadrilateral in destination image space.

An affine transform is fully determined by the mapping of 3 discrete points. The following primitives compute an affine transformation matrix that maps the first three corners of the source quad are mapped to the first three vertices of the destination image quad. If the fourth vertices do not match the transform, an `NPP_AFFINE_QUAD_INCORRECT_WARNING` is returned by the primitive.

#### 7.78.3.2 NppStatus nppiGetAffineQuad (NppiRect oSrcROI, double aQuad[4][2], const double aCoeffs[2][3])

This method computes the quadrilateral in the destination image that the source ROI is transformed into by the affine transformation expressed by the coefficients array (aCoeffs).

**Parameters:**

- oSrcROI** The source ROI.

*aQuad* The resulting destination quadrangle.

*aCoeffs* The affine transform coefficients.

- [NPP\\_RECT\\_ERROR](#) Indicates an error condition if width or height of the intersection of the oSrcROI and source image is less than or equal to 1
- [NPP\\_COEFF\\_ERROR](#) Indicates an error condition if coefficient values are invalid

#### 7.78.3.3 NppStatus nppiGetAffineTransform (NppiRect oSrcROI, const double aQuad[4][2], double aCoeffs[2][3])

Computes affine transform coefficients based on source ROI and destination quadrilateral.

The function computes the coefficients of an affine transformation that maps the given source ROI (axis aligned rectangle with integer coordinates) to a quadrilateral in the destination image.

An affine transform in 2D is fully determined by the mapping of just three vertices. This function's API allows for passing a complete quadrilateral effectively making the problem overdetermined. What this means in practice is, that for certain quadrilaterals it is not possible to find an affine transform that would map all four corners of the source ROI to the four vertices of that quadrilateral.

The function circumvents this problem by only looking at the first three vertices of the destination image quadrilateral to determine the affine transformation's coefficients. If the destination quadrilateral is indeed one that cannot be mapped using an affine transformation the function informs the user of this situation by returning a [NPP\\_AFFINE\\_QUAD\\_INCORRECT\\_WARNING](#).

#### Parameters:

*oSrcROI* The source ROI. This rectangle needs to be at least one pixel wide and high. If either width or height are less than one an [NPP\\_RECT\\_ERROR](#) is returned.

*aQuad* The destination quadrilateral.

*aCoeffs* The resulting affine transform coefficients.

#### Returns:

Error codes:

- [NPP\\_SIZE\\_ERROR](#) Indicates an error condition if any image dimension has zero or negative value
- [NPP\\_RECT\\_ERROR](#) Indicates an error condition if width or height of the intersection of the oSrcROI and source image is less than or equal to 1
- [NPP\\_COEFF\\_ERROR](#) Indicates an error condition if coefficient values are invalid
- [NPP\\_AFFINE\\_QUAD\\_INCORRECT\\_WARNING](#) Indicates a warning when quad does not conform to the transform properties. Fourth vertex is ignored, internally computed coordinates are used instead

## Backwards Perspective Transform

Transforms (warps) an image based on a perspective transform.

The perspective transform is given as a  $3 \times 3$  matrix  $C$ . A pixel location  $(x, y)$  in the source image is mapped to the location  $(x', y')$  in the destination image. The destination image coordinates fulfill the following properties:

$$x = \frac{c_{00} * x' + c_{01} * y' + c_{02}}{c_{20} * x' + c_{21} * y' + c_{22}} \quad y = \frac{c_{10} * x' + c_{11} * y' + c_{12}}{c_{20} * x' + c_{21} * y' + c_{22}}$$

$$C = \begin{bmatrix} c_{00} & c_{01} & c_{02} \\ c_{10} & c_{11} & c_{12} \\ c_{20} & c_{21} & c_{22} \end{bmatrix}$$

In other words, given matrix  $C$  the source image's shape is transformed to the destination image using the inverse matrix  $C^{-1}$ :

$$M = C^{-1} = \begin{bmatrix} m_{00} & m_{01} & m_{02} \\ m_{10} & m_{11} & m_{12} \\ m_{20} & m_{21} & m_{22} \end{bmatrix} \quad x' = \frac{c_{00} * x + c_{01} * y + c_{02}}{c_{20} * x + c_{21} * y + c_{22}} \quad y' = \frac{c_{10} * x + c_{11} * y + c_{12}}{c_{20} * x + c_{21} * y + c_{22}}$$

32-bit floating point complex to 32-bit floating point magnitude.

Converts complex-number pixel image to single channel image computing the result pixels as the magnitude of the complex values.

#### Parameters:

**pSrc** Source-Image Pointer.  
**nSrcStep** Source-Image Line Step.

32-bit floating point complex to 32-bit floating point squared magnitude.

Converts complex-number pixel image to single channel image computing the result pixels as the squared magnitude of the complex values.

The squared magnitude is an intermediate result of magnitude computation and can thus be computed faster than actual magnitude. If magnitudes are required for sorting/comparing only, using this function instead of `nppiMagnitude_32fc32f_C1R` can be a worthwhile performance optimization.

## 7.88 Sum

Primitives for computing the sum of all the pixel values in an image.

### Sum

Given an image  $pSrc$  with width  $W$  and height  $H$ , the sum will be computed as

$$Sum = \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} pSrc(j, i)$$

All the results are stored in a 64-bit double precision format, except for two primitives `npSum_8u64s_C1R` and `npSum_8u64s_C4R`.

The sum functions require additional scratch buffer for computations.

## 7.95 Mean

Primitives for computing the arithmetic mean of all the pixel values in an image.

### Mean

Given an image  $pSrc$  with width  $W$  and height  $H$ , the arithmetic mean will be computed as

$$Mean = \frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} pSrc(j, i)$$

The mean functions require additional scratch buffer for computations.

## 7.96 Mean\_StdDev

Primitives for computing both the arithmetic mean and the standard deviation of an image.

### Mean\_StdDev

Given an image  $pSrc$  with width  $W$  and height  $H$ , the mean and the standard deviation will be computed as

$$Mean = \frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} pSrc(j, i)$$

$$StdDev = \sqrt{\frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} (pSrc(j, i) - Mean)^2}$$

The Mean\_StdDev primitives require additional scratch buffer for computations.

### 7.97.1 Detailed Description

Primitives for computing the norms of an image, the norms of difference, and the relative errors of two images.

Given an image  $pSrc$  with width  $W$  and height  $H$ ,

1. The infinity norm ([Norm\\_Inf](#)) is defined as the largest absolute pixel value of the image.
2. The L1 norm ([Norm\\_L1](#)) is defined as the sum of the absolute pixel value of the image, i.e.,

$$Norm\_L1 = \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc(j, i)|$$

3. The L2 norm (Norm\_L2) is defined as the square root of the sum of the squared absolute pixel value of the image, i.e.,

$$Norm\_L2 = \sqrt{\sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc(j, i)|^2}$$

Given two images *pSrc1* and *pSrc2* both with width *W* and height *H*,

1. The infinity norm of difference (NormDiff\_Inf) is defined as the largest absolute difference between pixels of two images.
2. The L1 norm of difference (NormDiff\_L1) is defined as the sum of the absolute difference between pixels of two images, i.e.,

$$NormDiff\_L1 = \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc1(j, i) - pSrc2(j, i)|$$

3. The L2 norm of difference (NormDiff\_L2) is defined as the squared root of the sum of the squared absolute difference between pixels of two images, i.e.,

$$NormDiff\_L2 = \sqrt{\sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc1(j, i) - pSrc2(j, i)|^2}$$

Given two images *pSrc1* and *pSrc2* both with width *W* and height *H*,

1. The relative error for the infinity norm of difference (NormRel\_Inf) is defined as NormDiff\_Inf divided by the infinity norm of the second image, i.e.,

$$NormRel\_Inf = \frac{NormDiff\_Inf}{Norm\_Inf_{src2}}$$

2. The relative error for the L1 norm of difference (NormRel\_L1) is defined as NormDiff\_L1 divided by the L1 norm of the second image, i.e.,

$$NormRel\_L1 = \frac{NormDiff\_L1}{Norm\_L1_{src2}}$$

3. The relative error for the L2 norm of difference (NormRel\_L2) is defined as NormDiff\_L2 divided by the L2 norm of the second image, i.e.,

$$NormRel\_L2 = \frac{NormDiff\_L2}{Norm\_L2_{src2}}$$

The norm functions require the addition device scratch buffer for the computations.

## 7.107 DotProd

Primitives for computing the dot product of two images.

### DotProd

Given two images  $pSrc1$  and  $pSrc2$  both with width  $W$  and height  $H$ , the dot product will be computed as

$$DotProd = \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} [pSrc1(j, i) \cdot pSrc2(j, i)]$$

The functions require additional scratch buffer for computations.

### 7.113.1 Detailed Description

Primitives for computing the standard deviation of the integral images.

The function computes the standard deviation of the pixel in the rectangular window with the integral image *pSrc* and the squared integral image *pSqr*, which can be obtained by calling [Integral](#) and [SqrIntegral](#).

The standard deviation of the pixel  $(j, i)$  can be computed using the formula:

$$pDst(j, i) = \sqrt{\max(0, \frac{\sum(SqrIntegral) \cdot N - (\sum(Integral))^2}{N^2})}$$

where  $\sum(SqrIntegral) = pSqr[j + oRect.y + oRect.height, i + oRect.x + oRect.width] - pSqr[j + oRect.y, i + oRect.x + oRect.width] - pSqr[j + oRect.y + oRect.height, i + oRect.x] + pSqr[j + oRect.y, i + oRect.x]$ ,  $\sum(Integral) = pSrc[j + oRect.y + oRect.height, i + oRect.x + oRect.width] - pSrc[j + oRect.y, i + oRect.x + oRect.width] - pSrc[j + oRect.y + oRect.height, i + oRect.x] + pSrc[j + oRect.y, i + oRect.x]$ ,  $N = oRect.width \cdot oRect.height$ .

The size of the *pSrc* and *pSqr* should be  $(oSizeROI.width + oRect.x + oRect.width, oSizeROI.height + oRect.y + oRect.height)$ .

## 7.114 HistogramEven

Primitives for computing the histogram of an image with evenly distributed bins.

### HistogramEven

The *nLowerLevel* (inclusive) and *nUpperLevel* (exclusive) define the boundaries of the range, which are evenly segmented into  $nLevel - 1$  bins.

The computed histogram is stored in *pHist*. The levels are calculated by another primitive [nppiEvenLevelsHost\\_32s](#) and are stored in a host pointer *hpLevels*. The number of levels is also  $nLevel - 1$ . The histogram  $pHist[k]$  is defined as the total number of pixels that fall into the range:  $hpLevels[k] \leq pSrc(j, i) < hpLevels[k + 1]$ . The functions require additional scratch buffer for computations.

## 7.115 HistogramRange

Primitives for computing the histogram of an image within specified ranges.

### HistogramEven

The histogram is computed according to the ranges provided in *pLevels*.

The histogram  $pHist[k]$  is defined as the total number of pixels that fall into the range:  $pLevels[k] \leq pSrc(j, i) < pLevels[k + 1]$ . The number of the histogram bins is  $nLevel - 1$ . The functions require additional scratch buffer for computations.

### 7.116.1 Detailed Description

Primitives for computing the proximity measure between a source image and a template image.

### 7.116.2 General Introduction

There are basically two approaches to compute the proximity measure for template matching, Euclidean distance and the cross correlation.

1. Euclidean distance computes the sum of the squared distance (SSD) between the corresponding pixels of the source image and the template image. The smaller the distance is, the more similar the source image and the template image is around the pixel. The anchor of the template image is used during the computations, which always lies in the geometric center of the image. Given a source image  $pSrc$  ( $W_s \times H_s$ ) and a template image  $pTpl$  ( $W_t \times H_t$ ), the Euclidean distance  $D_{st}(c, r)$  between two images at pixel in row  $r$  and column  $c$  is computed as ( $s$  stands for source image and  $t$  for template image for short):

$$D_{st}(c, r) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} [pTpl(j, i) - pSrc(j + c - \frac{H_t}{2}, i + r - \frac{W_t}{2})]^2$$

2. Cross correlation computes the sum of the product between the corresponding pixels of the source image and the template image. The cross correlation  $R_{st}(c, r)$  is calculated as:

$$R_{st}(c, r) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} [pTpl(j, i) \cdot pSrc(j + c - \frac{H_t}{2}, i + r - \frac{W_t}{2})]$$

The larger the cross correlation value is, the more similar the source image and the template image is around the pixel.

3. The cross correlation  $R_{st}(c, r)$  is affected by the brightness of the images which may vary due to the lighting and exposure conditions. Therefore, NPP computes the cross correlation coefficient to circumvent this dependence. This is typically done at every step by subtracting the mean from every pixel value, i.e.,

$$\tilde{R}_{st}(c, r) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} [pTpl(j, i) - Mean_t] \cdot [pSrc(j + c - \frac{H_t}{2}, i + r - \frac{W_t}{2}) - Mean_s]$$

NPP computes the normalized values of Euclidean distance, cross correlation and the cross correlation coefficient.

1. The normalized Euclidean distance  $\sigma_{st}(c, r)$  is defined as:

$$\sigma_{st}(c, r) = \frac{D_{st}(c, r)}{\sqrt{R_{ss}(c, r) \cdot R_{tt}(\frac{H_t}{2}, \frac{W_t}{2})}}$$

2. The normalized cross correlation  $\rho_{st}(c, r)$  is defined as:

$$\rho_{st}(c, r) = \frac{R_{st}(c, r)}{\sqrt{R_{ss}(c, r) \cdot R_{tt}(\frac{H_t}{2}, \frac{W_t}{2})}}$$

The  $R_{ss}(c, r)$  and  $R_{tt}(\frac{H_t}{2}, \frac{W_t}{2})$  denote the auto correlation of the source image and the template image individually. They are defined as:

$$R_{ss}(c, r) = \sum_{j=c-\frac{H_t}{2}}^{c+\frac{H_t}{2}} \sum_{i=r-\frac{W_t}{2}}^{r+\frac{W_t}{2}} pSrc(j, i)$$

$$R_{tt}(\frac{H_t}{2}, \frac{W_t}{2}) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} pTpl(j, i)$$

3. Similarly, the normalized cross correlation coefficient  $\gamma_{st}(c, r)$  is calculated as:

$$\gamma_{st}(c, r) = \frac{\tilde{R}_{st}(c, r)}{\sqrt{\tilde{R}_{ss}(c, r) \cdot \tilde{R}_{tt}(\frac{H_t}{2}, \frac{W_t}{2})}}$$

The  $\tilde{R}_{ss}(c, r)$  and  $\tilde{R}_{tt}(\frac{H_t}{2}, \frac{W_t}{2})$  are defined as:

$$\tilde{R}_{ss}(c, r) = \sum_{j=c-\frac{H_t}{2}}^{c+\frac{H_t}{2}} \sum_{i=r-\frac{W_t}{2}}^{r+\frac{W_t}{2}} [pSrc(j, i) - Mean_s]$$

$$\tilde{R}_{tt}(\frac{H_t}{2}, \frac{W_t}{2}) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} [pTpl(j, i) - Mean_t]$$

### 7.116.3 Categorizations

The Euclidean distance and the cross correlation are categorized into three types, full, same, and valid.

1. Full mode indicates that the anchor of the template image starts from the outside of the source image, assuming the out-of-boundary pixels are zero-padded. The size of the destination image is  $(W_s + W_t - 1) \times (H_s + H_t - 1)$ .
2. Same mode means that the anchor of the template image starts from the top left pixel of the source image. All the out-of-boundary pixels are also zero-padded. The size of the destination image is the same as the source one, i.e.,  $W_s \times H_s$ .
3. Valid mode indicates that there are no out-of-boundary readings from the source image. The anchor of the template image starts from the inside of the source image. The size of the destination image is  $(W_s - W_t + 1) \times (H_s - H_t + 1)$ .
